

Network Issue Summary - June 29, 2026

Summary for the network logs captured on June 29, 2026.

Overall conclusion:

The issue is intermittent network loss, not a clean Wi-Fi disconnect most of the time.

The WSL interface eth2 usually stays up, keeps the same IP address 192.168.2.36, and often still has the default route and DNS working.

What happened:

- Several times, external internet failed while the gateway 192.168.2.1 was still reachable. This means the local network stayed up, but internet beyond the router failed.
- A few times, the gateway itself became unreachable. This means the problem was between WSL/Windows and the router, or the router briefly stopped responding.
- At least once, the default route disappeared briefly. This points to a local network stack or routing issue.
- At least once, ping, gateway, and DNS all failed together, then recovered within about 2 seconds. This is a stronger local outage event.

Times when internet was lost while the gateway was still reachable:

- 12:57:08
- 12:58:38
- 12:59:13
- 12:59:35
- 12:59:45
- 13:02:55
- 13:03:12
- 13:03:34
- 13:11:10
- 13:11:43
- 13:14:33
- 13:15:53

Most important outage times:

- 12:56:13: gateway unreachable.
- 13:06:45: default route missing, restored at 13:06:47.
- 13:13:34: gateway unreachable and DNS failed, restored at 13:13:36.

Pattern seen in the logs:

- Local gateway instability happened a few times.
- Internet beyond the router failed many times.
- WSL interface eth2 stayed up, so the problem is not simply interface down.

Practical interpretation:

The logs point to unstable connectivity between the machine and the router, plus repeated upstream internet failures after the router. This does not look like only a website problem, only a DNS problem, or a permanent adapter failure.
